Generating Random Logic Programs Using Constraint Programming

Paulius Dilkas[0000−1111−2222−3333]

University of Edinburgh, Edinburgh, UK
`p.dilkas@sms.ed.ac.uk`

Abstract. The abstract should briefly summarize the contents of the paper in 150–250 words.

Keywords: Constraint Programming · Logic Programming · Probabilistic Logic Programming.

1   Introduction

Motivation:

- Generating random programs that generate random data.
- Learning: how this can be used for (targeted) learning, when (atomic) probabilities can be assigned based on counting and we can have extra constraints. A more primitive angle: generate structures, learn weights.

We will often use $\square$ as a special domain value to indicate some kind of exception. We write $\texttt{a}[b] \in c$ to mean that $\texttt{a}$ is an array of variables of length b such that each element of $\texttt{a}$ has domain c. Similarly, we write $\texttt{c}[b]\ \texttt{a}$ to denote an array $\texttt{a}$ of length b such that each element of $\texttt{a}$ has type $\texttt{c}$. All constraint variables in the model are integer variables, but, e.g., if the integer i refers to a logical variable X, we will use i and X interchangeably. All indices start at zero.

We also use Choco 4.10.2 [3]. This works with both Prolog [1] and ProbLog [4]. Tested with SWI-Prolog [5].

1.1   TODO

- Heads are too restrictive: $\mathsf{P}(X, Y, X)$ should be allowed.
- A constraint for logical equivalence. An algorithm to reduce each tree to some kind of normal form.
- Perhaps negative cycle detection could use the same graph as the independence propagator? If we extend each domain to -1, 0, 1, but that might make propagation weaker or slower.
- Could investigate how uniform the generated distribution of programs is. Distributions of individual parameters will often favour larger values because, e.g., there are more 5-tuples than 4-tuples.

- Inference options to explore. Logspace vs normal space. Symbolic vs non-symbolic. Propagate evidence (might be irrelevant)? Propagate weights? Supported knowledge compilation techniques: sdd, sddx, bdd, nnf, ddnnf, kbest, fsdd, fbdd.
- Mention the random heuristic. Mention that restarting gives better randomness, but duplicates become possible. Restarting after each run is expensive. Periodic restarts could be an option.

1.2   Parameters

Parameters:

- a list of predicates $\mathcal{P}$,
- a list of their arities $\mathcal{A}$ (including zero),
  - maximum arity $\mathcal{M}_\mathcal{A} := \max \mathcal{A}$.
- a list of variables $\mathcal{V}$,
- and a list of constants $\mathcal{C}$.
  - Each of them can be empty, but $|\mathcal{C}| + |\mathcal{V}| > 0$.
- a list of probabilities that are randomly assigned to clauses,
- option to forbid all cycles or just negative cycles,
- $\mathcal{M}_\mathcal{N} \geq 1$: maximum number of nodes in the tree representation of a clause,
- $\mathcal{M}_\mathcal{C} \geq |\mathcal{P}|$: maximum number of clauses in a program,
- maximum number of solutions,

We also define $\mathcal{T} = \{\neg, \wedge, \vee, \top\}$. All decision variables of the model are contained in two arrays:

- `Body[`$\mathcal{M}_\mathcal{C}$`] bodiesOfClauses`,
- `Head[`$\mathcal{M}_\mathcal{C}$`] headsOfClauses`

2   Heads of Clauses

Our definition is slightly more involved because we want to eliminate some symmetries.

Definition 1. *The* head *of a clause is composed of:*

- *a* `predicate` $\in \mathcal{P} \cup \{\square\}$*, where $\square$ denotes a disabled clause,*
- *and* `arguments[`$\mathcal{M}_\mathcal{A}$`]` $\in \mathcal{C} \cup \mathcal{V}$*.*

Definition 2. *The* `predicate`*'s* `arity` $\in [0, \mathcal{M}_\mathcal{A}]$ *can then be defined using the* `table` *constraint as*

$$\mathtt{arity} = \begin{cases} 0 & \textit{if } \mathtt{predicate} = \square \\ \textit{the arity of } \mathtt{predicate} & \textit{otherwise.} \end{cases}$$

Constraint 1 *For $i = 0, \ldots, \mathcal{M}_\mathcal{A} - 1$,*

$$i \geq \mathtt{arity} \implies \mathtt{arguments}[i] = 0.$$

Definition 3. *We define an array* occurrences *of* $|\mathcal{V}|$ *sets such that, for all* $v \in \mathcal{V}$, occurrences$[v]$ *is a subset of* $\{0, \ldots, \mathcal{M}_{\mathcal{A}} - 1\}$ *that stores the indices of* arguments *at which* v *is located. It is defined by the* setsIntsChanneling *constraint equivalent to the following condition: for* $i = 0, \ldots, \mathcal{M}_{\mathcal{A}} - 1$ *and* $v \in \mathcal{V}$,

$$\text{arguments}[i] = v \quad \Longleftrightarrow \quad i \in \text{occurrences}[v].$$

Definition 4. *We define a* $|\mathcal{V}| \times 2$ *matrix* $\mathbf{M}$ *with domain* $[0, \mathcal{M}_{\mathcal{A}}]$ *such that for* $v = 0, \ldots, |\mathcal{V}| - 1$,

$$\mathbf{M}_{v,0} = |\text{occurrences}[v]|.$$

$$\mathbf{M}_{v,1} = \begin{cases} \min \text{occurrences}[v] & \text{if occurrences}[v] \neq \emptyset \\ 0^1 & \text{otherwise.} \end{cases}$$

Constraint 2 *We can then impose the* lexChainLessEq *constraint on* $\mathbf{M}$ *which means that for* $v = 1, \ldots, |\mathcal{V}| - 1$,

$$|\text{occurrences}[v-1]| \leq |\text{occurrences}[v]|,$$

and if $|\text{occurrences}[v-1]| = |\text{occurrences}[v]| > 0$, *then*

$$\min \text{occurrences}[v-1] \leq \min \text{occurrences}[v].$$

Example 1. Let $\mathcal{M}_{\mathcal{A}} = 4$, $\mathsf{P} \in \mathcal{P}$, $\mathcal{V} = \{X, Y, Z\}$. Then $\mathsf{P}(Z, Y, Z)$ would be represented as:

$$\text{predicate} = \mathsf{P},$$
$$\text{arguments} = [Z, Y, Z, 0],$$
$$\text{arity} = 3,$$
$$\text{occurrences} = [\emptyset, \{1\}, \{0, 2\}],$$
$$\mathbf{M} = \begin{bmatrix} 0 & 0 \\ 1 & 1 \\ 2 & 0 \end{bmatrix}.$$

3   Bodies of Clauses

Definition 5. *The body of a clause is defined by:*

- treeStructure$[\mathcal{M}_{\mathcal{N}}] \in [0, \mathcal{M}_{\mathcal{N}} - 1]$ *such that:*
  - treeStructure$[i] = i$: *the* i-*th node is a root.*
  - treeStructure$[i] = j$: *the* i-*th node's parent is node* j.
- Node$[\mathcal{M}_{\mathcal{N}}]$ treeValues.

Auxiliary variables: numNodes, numTrees $\in \{1, \ldots, \mathcal{M}_{\mathcal{N}}\}$. The former counts the number of nodes in the main tree. The latter counts the number of trees in total.
---

[1] This could be any fixed value in the domain.

Fig. 1. A tree representation of the formula from Example 2

Example 2. Let $\mathcal{M}_\mathcal{N} = 8$. Then $\neg\mathsf{P}(X) \vee (\mathsf{Q}(X) \wedge \mathsf{P}(X))$ corresponds to the tree in Fig. 1 and can be encoded as:

$$\mathtt{treeStructure} = [0, 0, 0, \quad 1, \quad 2, \quad 2, \ 6, 7],$$
$$\mathtt{treeValues} = [\vee, \neg, \wedge, \mathsf{P}(X), \mathsf{Q}(X), \mathsf{P}(X), \top, \top],$$
$$\mathtt{numNodes} = 6,$$
$$\mathtt{numTrees} = 3.$$

In the rest of this section, we will describe how the elements of $\mathtt{treeValues}$ are encoded and list a series of constraints that make this representation unique.

3.1 Nodes

Definition 6. *A* node *has a* $\mathtt{name} \in \mathcal{T} \cup \mathcal{P}$ *and* $\mathtt{arguments}[\mathcal{M}_\mathcal{A}] \in \mathcal{V} \cup \mathcal{C}$. *The node's* $\mathtt{arity} \in [0, \mathcal{M}_\mathcal{A}]$ *is defined by a* $\mathtt{table}$ *constraint as*

$$\mathtt{arity} = \begin{cases} \text{the arity of } \mathtt{name} & \text{if } \mathtt{name} \in \mathcal{P} \\ 0 & \text{otherwise.} \end{cases}$$

Constraint 3 *For* $i = 0, \ldots, \mathcal{M}_\mathcal{A} - 1$,

$$i \geq \mathtt{arity} \implies \mathtt{arguments}[i] = 0^2.$$

Example 3. Let $\mathcal{M}_\mathcal{A} = 2$, $\mathcal{P} = [\mathsf{P}, \ldots]$, $\mathcal{A} = [1, \ldots]$, and $X \in \mathcal{V}$. Then the node representing atom $\mathsf{P}(X)$ has:

$$\mathtt{name} = \mathsf{P},$$
$$\mathtt{arguments} = [X, 0],$$
$$\mathtt{arity} = 1.$$

3.2 Constraints

Constraint 4 $\mathtt{treeStructure}$ *represents* $\mathtt{numTrees}$ *trees, i.e.,*

$$\mathtt{tree}(\mathtt{treeStructure}, \mathtt{numTrees})^3.$$

---

[2] Zero here represents the first variable or constant, regardless of what it is.
[3] This constraint uses dominator-based filtering by Fages and Lorca [2].

Constraint 5 $\texttt{treeStructure}[0] = 0$.

Constraint 6 $\texttt{numTrees} + \texttt{numNodes} = \mathcal{M}_{\mathcal{N}} + 1$.

Constraint 7 $\texttt{treeStructure}$ *is sorted.*

Constraint 8 *For* $i = 0, \ldots, \mathcal{M}_{\mathcal{N}} - 1$, *if* $\texttt{numNodes} \leq i$, *then*

$$\texttt{treeStructure}[i] = i \quad and \quad \texttt{treeValues}[i].\texttt{name} = \top,$$

else

$$\texttt{treeStructure}[i] < \texttt{numNodes}.$$

Constraint 9 *For* $i = 0, \ldots, \mathcal{M}_{\mathcal{N}} - 1$,

$$\texttt{count}(i, \texttt{treeStructure}_{-i}) = 0 \iff \texttt{treeValues}[i].\texttt{name} \in \mathcal{P} \cup \{\top\},$$
$$\texttt{count}(i, \texttt{treeStructure}_{-i}) = 1 \iff \texttt{treeValues}[i].\texttt{name} = \neg,$$
$$\texttt{count}(i, \texttt{treeStructure}_{-i}) > 1 \iff \texttt{treeValues}[i].\texttt{name} \in \{\wedge, \vee\}.$$

$\texttt{treeStructure}_{-i}$ *denotes array* $\texttt{treeStructure}$ *with position i skipped.*

Each constraint corresponds to node i having no children, one child, and multiple children, respectively.

Constraint 10 *For* $i = 0, \ldots, \mathcal{M}_{\mathcal{N}} - 1$,

$$\texttt{treeStructure}[i] \neq i \implies \texttt{treeValues}[i].\texttt{name} \neq \top.$$

If the clause should be disabled, $\texttt{numNodes} = 1$ and $\texttt{treeValues}[0].\texttt{name} = \top$.

4   Managing Clauses

Constraint 11 *For* $i = 0, \ldots, \mathcal{M}_{\mathcal{C}} - 1$, *let* $p_i = \texttt{headsOfClauses}[i].\texttt{predicate}$. *Then* $(p_i)_{i=0}^{\mathcal{M}_{\mathcal{C}}-1}$ *is sorted.*

Constraint 12 *Each predicate gets at least one clause. Let*

$$P = \{h.\texttt{predicate} \mid h \in \texttt{headsOfClauses}\}.$$

Then

$$\texttt{nValues}(P) = \begin{cases} \texttt{numPredicates} + 1 & if \; \texttt{count}(\square, P) > 0 \\ \texttt{numPredicates} & otherwise. \end{cases}$$

Here, $\texttt{nValues}(P)$ *counts the number of unique values in P.*

Constraint 13 *Let* $\prec$ *be any total order defined over bodies of clauses, and let* $\preceq$ *be its extension with equality (in the same way as $\leq$ extends $<$). If*

$$\texttt{headsOfClauses}[i-1].\texttt{predicate} = \texttt{headsOfClauses}[i].\texttt{predicate},$$

then $\texttt{bodiesOfClauses}[i-1] \preceq \texttt{bodiesOfClauses}[i]$.

For example, $\preceq$ can be implemented as `lexLessEq` over the decision variables of each body.

Constraint 14 *Adjacency matrix representation:*

$$A[i][j] = 0 \iff \nexists k : \texttt{headsOfClauses}[k].\texttt{predicate} = j \text{ and}$$
$$i \in \{a.\texttt{name} \mid a \in \texttt{bodiesOfClauses}[k].\texttt{treeValues}\}.$$

5   Counting Programs

Let p_a be the number of predicates in $\mathcal{P}$ with arity $a \in \mathcal{A}$.

Number of atoms (leaves of the tree):

$$A = \sum_{a \in \mathcal{A}} p_a (|\mathcal{V}| + |\mathcal{C}|)^a$$

Number of clauses:

$$C = 1 + \sum_{n=1}^{\mathcal{M}_{\mathcal{N}}} T(n),$$

where $T(n)$ is defined recursively as:

$$T(1) = A$$

and

$$T(n) = T(n-1) + 2 \sum_{\substack{c_1 + \cdots + c_k = n-1, \\ k \geq 2, \\ c_i \geq 1 \text{ for all } i}} \prod_{i=1}^{k} T(c_i).$$

Example of ordered partitions:

$$3 = 2 + 1 = 2 + 1 = 1 + 1 + 1,$$

so for $n = 4$, the sum would have three terms.

Number of heads for a specific predicate with arity $a \in \mathcal{A}$:

$$H_a = |\mathcal{C}|^a + \sum_{v=1}^{a} \binom{a}{v} |\mathcal{C}|^{a-v} \sum_{k=0}^{|\mathcal{V}|-1} \binom{v-1}{k}.$$

First, select the v positions dedicated for variables. The remaining $a-v$ constants can then be filled in $|\mathcal{C}|^{a-v}$ ways. Filling v positions with $k+1$ variables in a non-decreasing manner (without skipping any variables) can be seen as putting k 'bars' in the $v-1$ spaces between v positions. Each bar represents switching to the next variable.

Let us order the elements of $\mathcal{P}$, and let a_i be the arity of the i-th predicate. The number of programs is then:

$$\sum_{\substack{\sum_{i=1}^{|\mathcal{P}|} h_i = n, \\ |\mathcal{P}| \le n \le \mathcal{M}_\mathcal{C}, \\ h_i \ge 1 \text{ for all } i}} \prod_{i=1}^{|\mathcal{P}|} \left(\binom{C}{h_i} \right) H_{a_i}^{h_i},$$

where

$$\left(\binom{n}{k} \right) = \binom{n+k-1}{k}.$$

This is without any kind of cycle detection and without probabilities.

6 Predicate Independence

Definition 7. *Let $\mathscr{P}$ be a probabilistic logic program. Its* predicate dependency graph *is a directed graph $G_{\mathscr{P}} = (V, E)$ with the set of nodes V consisting of all predicates in $\mathscr{P}$. We add an edge from predicate P to predicate Q if there is a clause in $\mathscr{P}$ with Q as the head and P mentioned in the body.*

Definition 8. *Let P be a predicate in a program $\mathscr{P}$. The* dependencies *of P is the smallest set D_P such that:*

- $\mathsf{P} \in D_\mathsf{P}$,
- *for every $\mathsf{Q} \in D_\mathsf{P}$, the nodes with arrows to Q in $G_{\mathscr{P}}$ are all in D_P.*

Definition 9. *Two predicates P and Q are* independent *if $D_\mathsf{P} \cap D_\mathsf{Q} = \emptyset$.*

A dependency is an algebraic data type that is either determined (in which case it holds only the index of the predicate) or undetermined (in which case it also holds the indices of the source and target vertices, corresponding to the edge responsible for making the dependency undetermined).

Propagation for independence:

- Two types of dependencies: determined and one-undetermined-edge-away-from-being-determined.
- Look up the dependencies of both predicates. For each pair of matching dependencies:
  - If both are determined, fail.
  - If one is determined, the selected edge of the other must not exist.

Algorithm 1: Propagation

Data: predicates p_1, p_2; adjacency matrix $\mathbf{A}$
for $(d_1, d_2) \in$ getDependencies$(p_1) \times$ getDependencies(p_2) *s.t.*
d_1.predicate $= d_2$.predicate **do**
    if d_1.isDetermined() **and** d_2.isDetermined() **then**
        fail();
    if d_1.isDetermined() **then**
        $\mathbf{A}[d_2$.source$][d_2$.target$]$.removeValue(1);
    else if d_2.isDetermined() **then**
        $\mathbf{A}[d_1$.source$][d_1$.target$]$.removeValue(1);

Algorithm 2: Entailment

Data: predicates p_1, p_2
$D \leftarrow \{(d_1, d_2) \in$ getDependencies$(p_1) \times$ getDependencies(p_2) $|$
d_1.predicate $= d_2$.predicate$\}$;
if $\{(d_1, d_2) \in D \mid d_1$.isDetermined()$, d_2$.isDetermined()$\} \neq \emptyset$ **then**
    return *FALSE*;
if $D = \emptyset$ **then**
    return *TRUE*;
return *UNDEFINED*;

Algorithm 3: Computing the dependencies of a predicate

Data: an $n \times n$ adjacency matrix $\mathbf{A}$
Function getDependencies(p):
    $D \leftarrow \{p\}$;
    repeat
        $D' \leftarrow D$;
        for $d \in D$ **do**
            for $i \leftarrow 1$ **to** n **do**
                edgeExists $\leftarrow \mathbf{A}[i][d$.predicate$] = \{1\}$;
                if edgeExists **and** d.isDetermined() **then**
                    $D' \leftarrow D' \cup \{i\}$;
                else if edgeExists **and not** d.isDetermined() **then**
                    $D' \leftarrow D' \cup \{(i, d$.source$, d$.target$)\}$;
                else if $|\mathbf{A}[i][d$.predicate$]| > 1$ **and** d.isDetermined() **then**
                    $D' \leftarrow D' \cup \{(i, i, d$.predicate$)\}$;
    until $D' = D$;
    return D;

7   Entailment Checking for Negative/All Cycles

1. Let C be a set of clauses such that their bodies and predicates in their heads are fully determined.
2. If $C = \emptyset$, return UNDEFINED.
3. Construct an adjacency list representation of a graph where vertices represent predicates. Each edge is either *positive* or *negative*. There is an edge from p to q if q appears in the body of a predicate with p as its head. The edge is negative if, when traversing the tree to reach some instance of q, we pass through a $\neg$ node. Otherwise, it's positive.
4. Run a modified cycle detection algorithm that detects all cycles that have at least one negative edge.
5. If we found a cycle, return FALSE.
6. If C encompasses all clauses, return TRUE.
7. Return UNDEFINED.
